

2.5 Proof by contradiction

2.5.1 Review practice

Question 1

For the statement, “if $n \% 3 = 1$, then $n \% 9 \neq 5$ ”, where $\%$ stands for “modulus”...

- a. What is the hypothesis p ?
- b. What is the conclusion q ?
- c. Using $\neg(p \rightarrow q) \equiv p \wedge \neg q$, write out the negation of this implication in English.

This negation can be used to build the counter-example, which we will use for the proof by contradiction.

There is extra space on the page

2.5.2 Proof by contradiction

Prove by contradiction: If n^2 is even, then n is even

Step 1: Identify the hypothesis and conclusion: Here, our **hypothesis** is “ n^2 is even”, and our **conclusion** is “ n is even”.

Step 2: Identify the negation: The negation of an implication is **not** an implication. A counter-example of this would be if we have $p \wedge \neg q$, or “ n^2 is even and n is odd”.

Step 3: Build a counter-example: Our counter-example is the scenario where the hypothesis is true and the conclusion is false... or in other words, the negation. **Counter-example:** “ n^2 is even and n is odd”

Step 4: Write the hypothesis & conclusion symbolically:
(For our counter-example implication)
 $n^2 = 2k$ (some even integer) $n = 2j + 1$ (some odd integer)

Step 5: Write equation: Using the statement, we are going to turn this into an equation. n is odd, and n^2 is even, so if we square the odd n to get the even n^2 , we would have... to get the even n^2 , we would have... $(2j + 1)^2 = 2k$

Step 6: Simplify until we have a contradiction:
 $(2j + 1)^2 = 2k$

$$\Rightarrow 4j^2 + 4j + 1 = 2k$$

$$\Rightarrow 1 = 2k - 4j^2 - 4j$$

$$\Rightarrow \frac{1}{2} = k - 2j^2 - 2j$$

Since k and j are both integers, through the closure property of integers (+, -, and \times results in an integer), we can show that $k - 2j^2 - 2j$ results in something that is *not an integer* – this is a contradiction. It shows that our counter-example is **false**, and no counter-example can exist.

Question 2

Prove by contradiction: If n^2 is odd, then n is odd.

Step 1: Identify the hypothesis and conclusion:

Hypothesis p :

Conclusion q :

Step 2: Identify the negation (counter-example):

p : _____ AND $\neg q$: _____

Step 3: Write the hypothesis & conclusion symbolically:

(Make sure you use different variables for n^2 and n .)

(p) $n^2 =$

($\neg q$) $n =$

Step 5: Write equation: Set the equation for n -squared equal to the equation for n^2 .

Step 6: Simplify until we have a contradiction:

Result:

Question 3

Use proof by contradiction to explain why it is impossible for a number n to be of the form $5k + 3$ and of $5j + 1$ for integers k and j .

Hint

$n = 5k + 3$ is one statement, and $n = 5j + 1$ is the other statement, so $5k + 3 = 5j + 1$ is your starting point.

This isn't in an implication form, so we begin at Step 5...

Step 5: Write equation: $5k + 3 = 5j + 1$

Step 6: Simplify until we have a contradiction:

Result:
