

## 2.5 Proof by contradiction

### 2.5.1 Review practice

#### Question 1

For the statement, “if  $n \% 3 = 1$ , then  $n \% 9 \neq 5$ ”, where  $\%$  stands for “modulus”...

- a. What is the hypothesis  $p$ ?  $n \% 3 = 1$
- b. What is the conclusion  $q$ ?  $n \% 9 \neq 5$
- c. Using  $\neg(p \rightarrow q) \equiv p \wedge \neg q$ , write out the negation of this implication in English.  $n \% 3 = 1$  and  $n \% 9 = 5$

This negation can be used to build the counter-example, which we will use for the proof by contradiction.

There is extra space on the page

## 2.5.2 Proof by contradiction

**Prove by contradiction:** If  $n^2$  is even, then  $n$  is even

**Step 1: Identify the hypothesis and conclusion:** Here, our **hypothesis** is “ $n^2$  is even”, and our **conclusion** is “ $n$  is even”.

**Step 2: Identify the negation:** A counter-example of this would be if we have  $p \wedge \neg q$ , or “ $n^2$  is even and  $n$  is odd”.

**Step 3: Build a counter-example:** While the negation of an implication is **not** an implication, we are using this negation in order to build a **new implication**: the contradiction.

**Counter-example:** “If  $n^2$  is even, then  $n$  is odd”

**Step 4: Write the hypothesis & conclusion symbolically:**  
(For our counter-example implication)  
 $n^2 = 2k$  (some even integer)       $n = 2j + 1$  (some odd integer)

**Step 5: Write equation:** Using the statement, we are going to turn this into an equation.  $n$  is odd, and  $n^2$  is even, so if we square the odd  $n$  to get the even  $n^2$ , we would have... to get the even  $n^2$ , we would have...  $(2j + 1)^2 = 2k$

**Step 6: Simplify until we have a contradiction:**  
 $(2j + 1)^2 = 2k$   
 $\Rightarrow 4j^2 + 4j + 1 = 2k$   
 $\Rightarrow 1 = 2k - 4j^2 - 4j$   
 $\Rightarrow \frac{1}{2} = k - 2j^2 - 2j$

Since  $k$  and  $j$  are both integers, through the closure property of integers (+, -, and  $\times$  results in an integer), we can show that  $k - 2j^2 - 2j$  results in something that is *not an integer* – this is a contradiction. It shows that our counter-example is **false**, and no counter-example can exist.

**Question 2**

Prove by contradiction: If  $n^2$  is odd, then  $n$  is odd.

**Step 1: Identify the hypothesis and conclusion:**

Hypothesis:  $n^2$  is odd

Conclusion:  $n$  is odd

**Step 2: Identify the negation:**

$n^2$  is odd AND  $n$  is even

**Step 3: Build a counter-example:**

IF  $n^2$  is odd THEN  $n$  is even

**Step 4: Write the hypothesis & conclusion symbolically:**

$$n^2 = 2k + 1$$

$$n = 2j$$

(Make sure you use different variables for  $n^2$  and  $n$ .)

**Step 5: Write equation:**  $2k + 1 = (2j)^2$ **Step 6: Simplify until we have a contradiction:**

$$2k + 1 = 4j^2$$

$$\Rightarrow 1 = 4j^2 - 2k$$

$$\Rightarrow \frac{1}{2} = 2j^2 - k$$

Result: The result is a fraction, not an integer, therefore no counter-example exists.

**Question 3**

Use proof by contradiction to explain why it is impossible for a number  $n$  to be of the form  $5k + 3$  and of  $5j + 1$  for integers  $k$  and  $j$ .

**Hint**

$n = 5k + 3$  is one statement, and  $n = 5j + 1$  is the other statement, so  $5k + 3 = 5j + 1$  is your starting point.

This isn't in an implication form, so we begin at Step 5...

**Step 5: Write equation:**  $5k + 3 = 5j + 1$

**Step 6: Simplify until we have a contradiction:**

$$\begin{aligned} 3 - 1 &= 5j - 5k \\ \Rightarrow 2 &= 5(j - k) \\ \Rightarrow \frac{2}{5} &= j - k \end{aligned}$$

Result: Since  $j$  is an integer and  $k$  is an integer,  $j - k$  must also be an integer. Here, we get a fraction, so the counter-example is invalid.
